

# Low Frequency Facility

*LFF is a Virgo INFN Commission II R&D experiment, to study, above and around 10 Hz, the noise of a 1cm Fabry*

*Perot cavity, suspended to a Virgo like suspension.*

Firenze-Urbino, Napoli (Solimeno),  
Pisa and Roma1

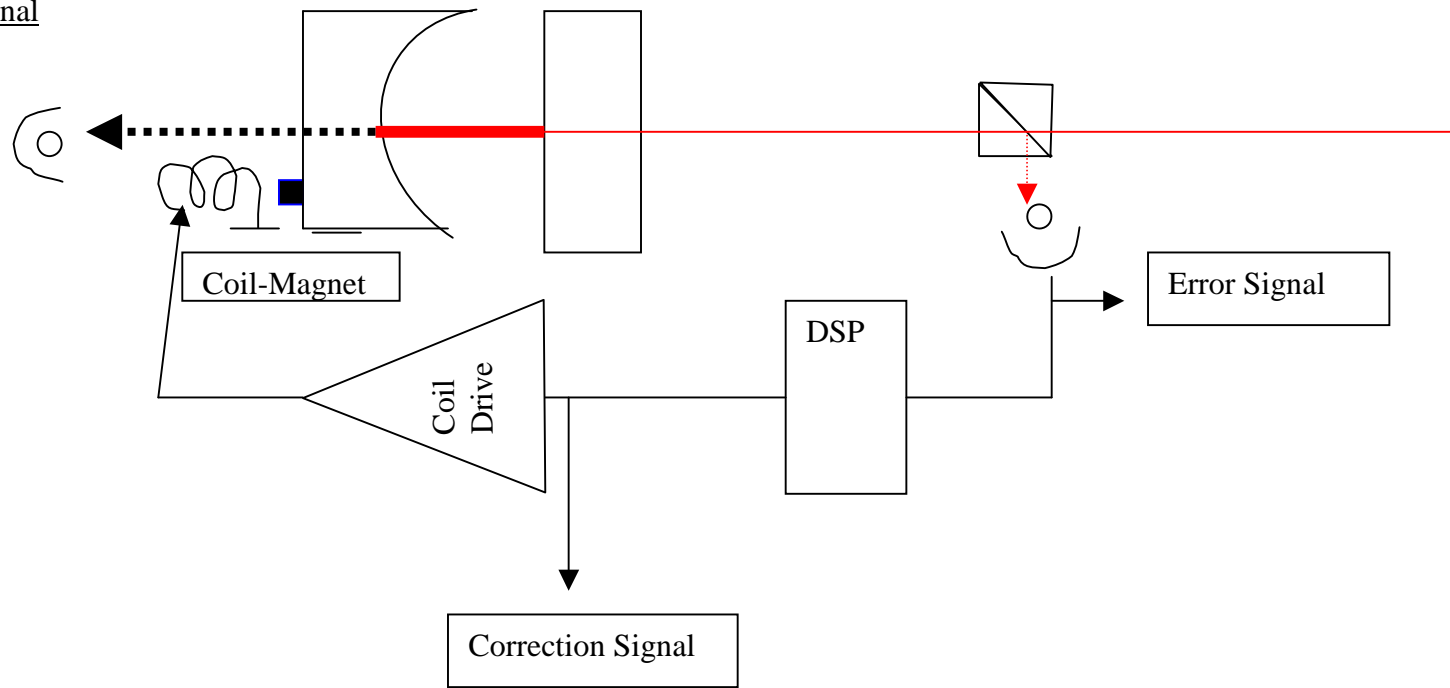

# Feed-Backs

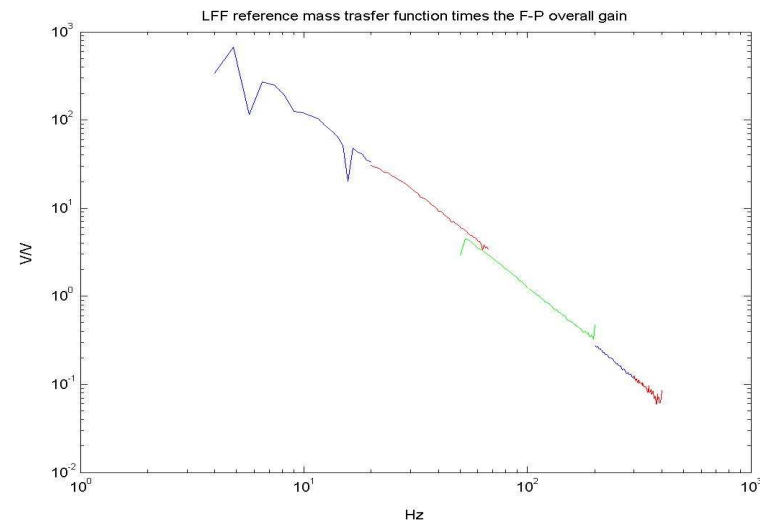

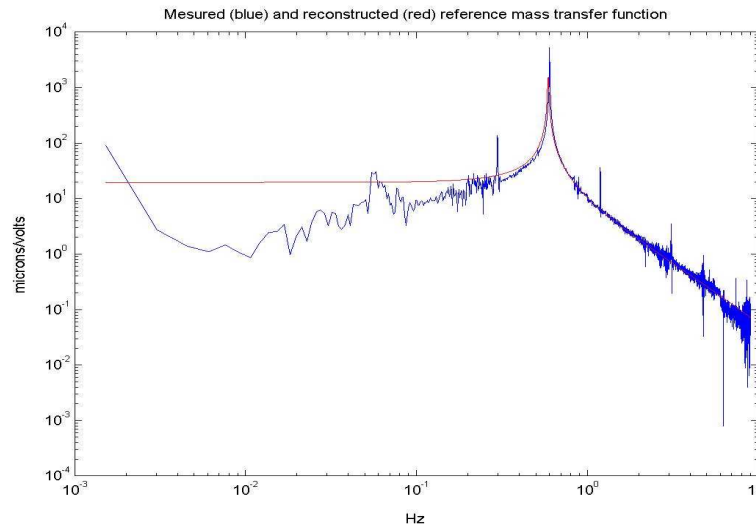

- Inertial Damping on
- Laser Frequency Stabilized
- Cavity longitudinally Locked using the Reference Mass
- Unity Gain Point around 100 Hz
- Feed Back stable for hours

Transmitted Signal

3 accelerometers measure seismic noise

# Low Frequency Calibration

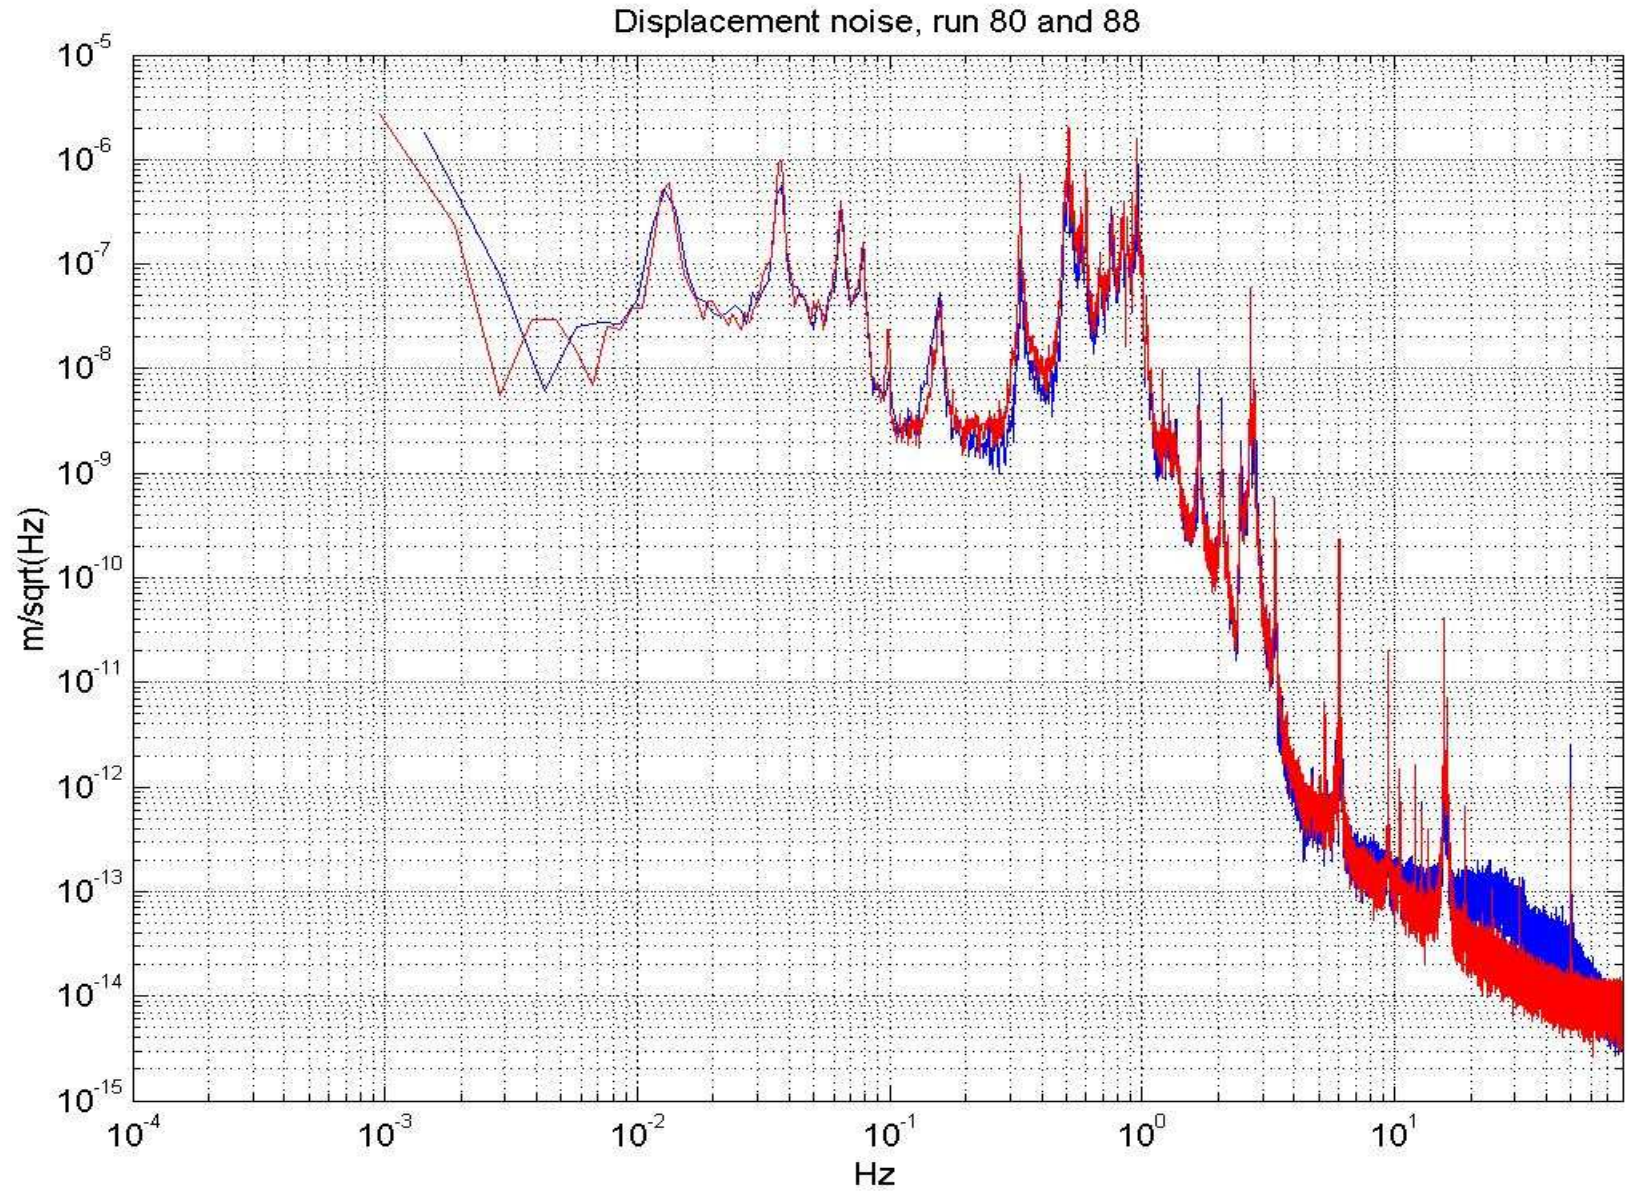

- Up to 9 Hz, Virgo Mirror transfer function measured using the array of LVDT
- From 5 to 400 Hz, the cavity mechanical transfer function has been directly measured (closed loop measurement).
- The cavity transfer function has been measured at very low frequency measuring the transmitted free spectral ranges (25, 30, 35 mHz, open loop)

**Cavity Transfer Function = Virgo Mirror Transfer Function**

# *Low Frequency Displacement Noise*

### Main Noise Contributions

# Coherence with Transmitted Power

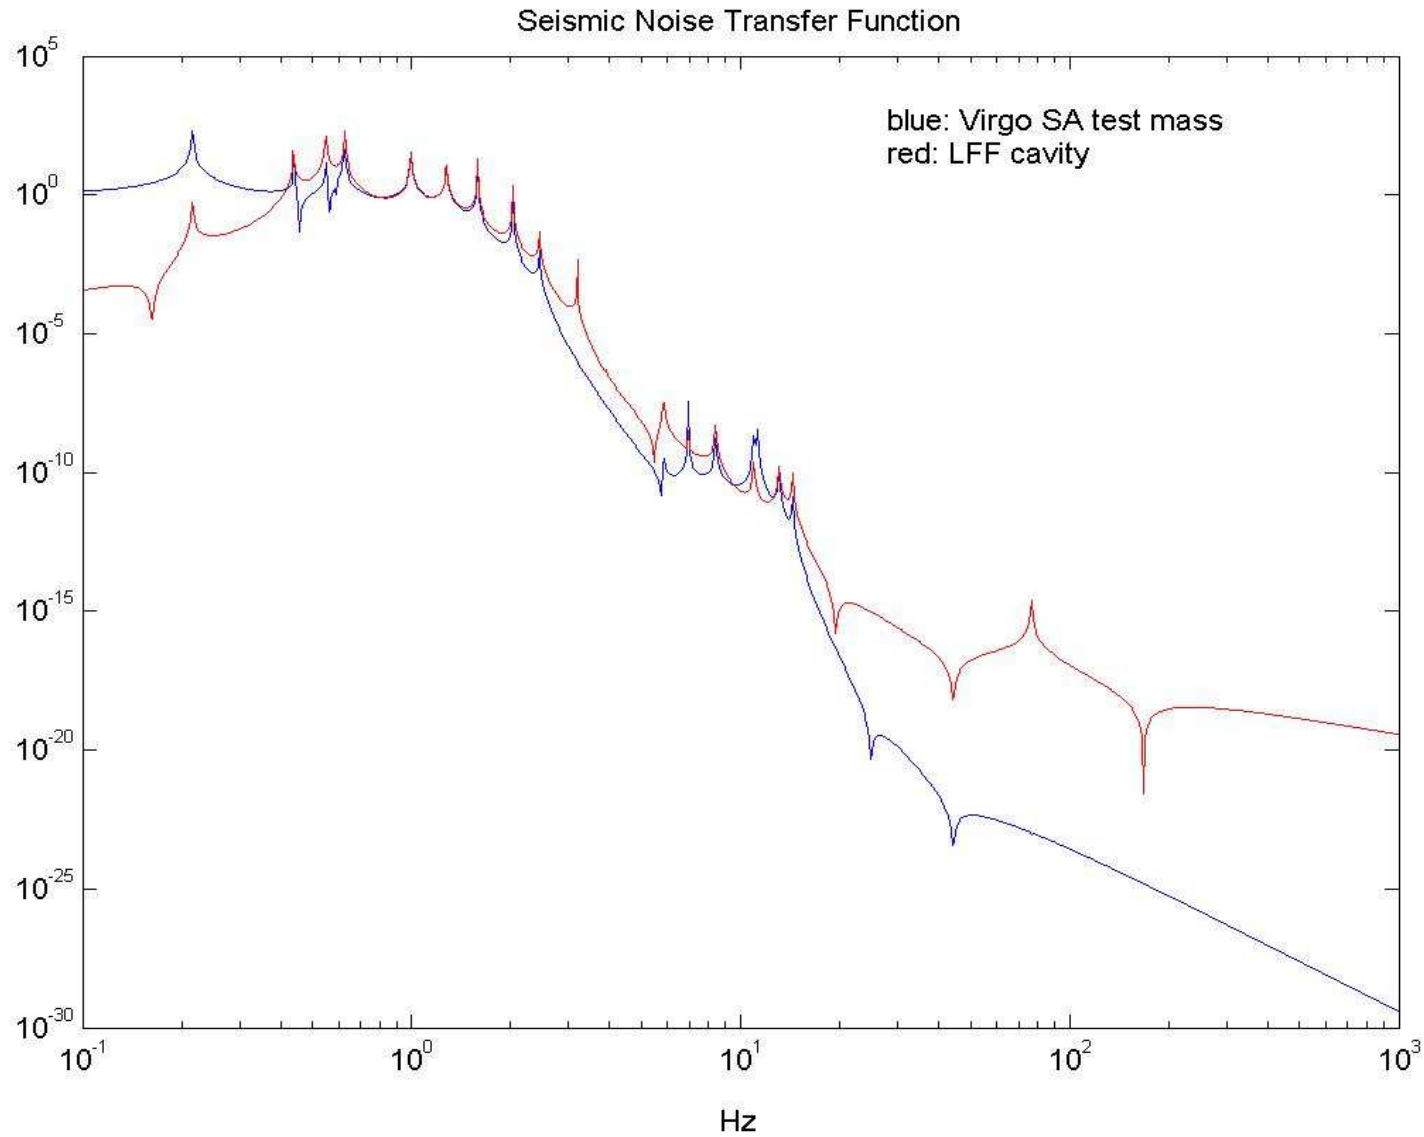

# Coherence with the Seismic Noise

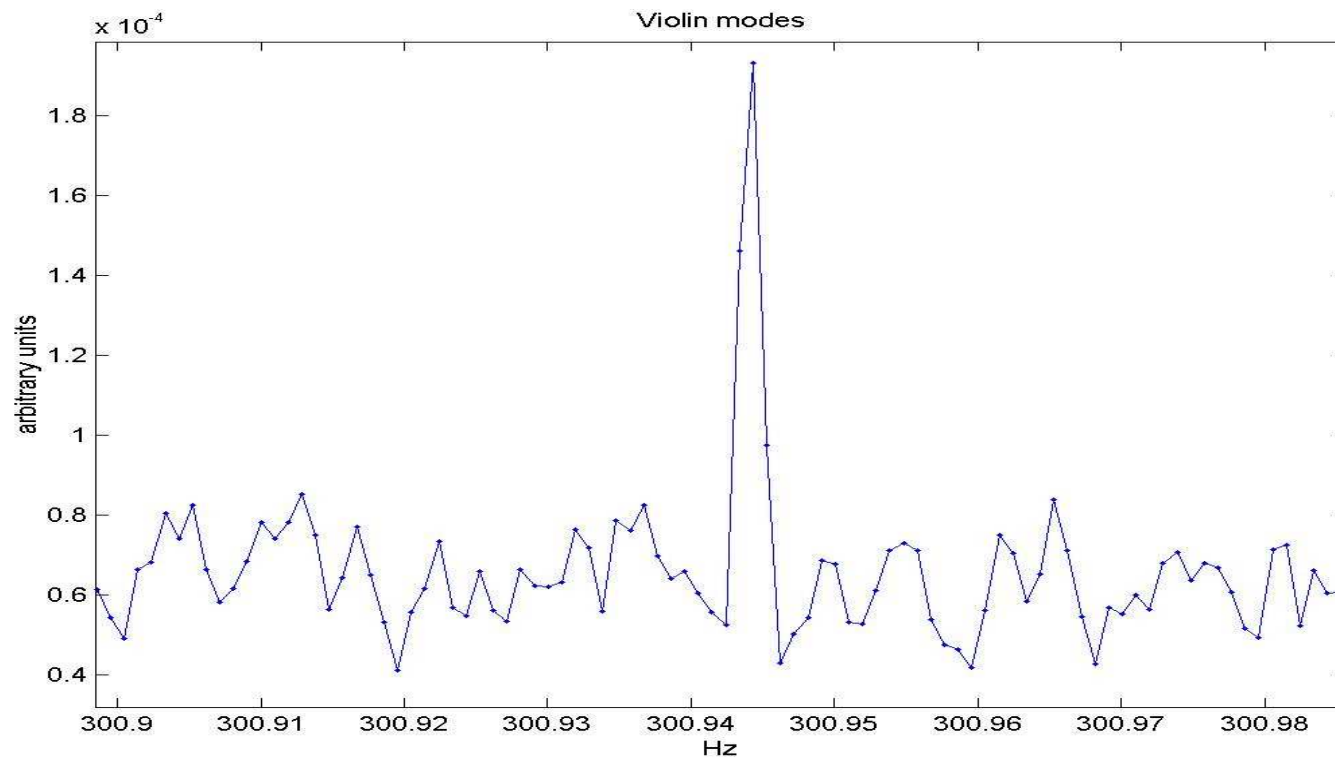

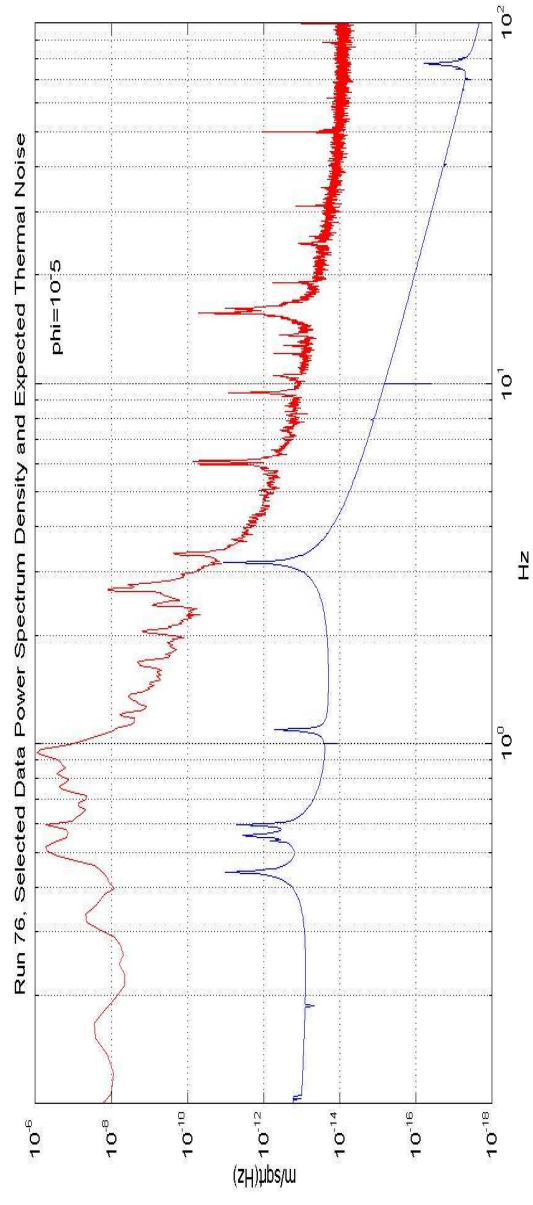

# Virgo Mirror and LFF Cavity Seismic Noise Transfer Functions (preliminary)

# Thermal Noise ?

- Several peaks are evident, work is in progress....

# Main Problems

- Finesse is lower than expected (alignment?), Inertial Damping Performance is not as good as 1 year ago, more than 1 FSR is transmitted (A. Di. Virgilio et al, “The LFF cavity used as a speed meter” , Phys. Lett. A, 2003)
- Large common mode rotation of the cavity below 1 Hz
- Cavity is a bit shorter (9 mm) and Sidebands (13MHz) are too close to the resonance
- Large DC in the error signal

# Future up to 2004

- Improve The Inertial Damping (new Inertial Damping)
  - Improve angular alignment as much as possible
  - Increase Frequency Modulation
  - Decrease Coil Driver Noise
  - Autoalignment?
- 
- Late 2003, upgrading and restoring of the LFF
